# Antarctic Meteorite Location Map Series

## INTRODUCTION

Antarctica has been a prolific source of meteorites since meteorite concentrations were discovered in 1969 (Yoshida *et al.*, 1971). Since 1976 the United States has joined Japan as the only nations that have sent expeditions specifically to search for meteorites. The U.S. program, currently under the direction of W. A. Cassidy (University of Pittsburgh), is supported by the U.S. National Science Foundation. The Antarctic Search For Meteorites (ANSMET) project has been active over much of the Trans-Antarctic Mountain Range. The first ANSMET expedition (a joint U.S.-Japanese effort) discovered what turned out to be a significant concentration of meteorites at the Allan Hills in Victoria Land (Cassidy, 1977; Cassidy, 1978; Cassidy, 1979). Later reconnaissance in this region resulted in the discovery of meteorite concentrations on icefields to the west of the Allan Hills, at Reckling Moraine, and Elephant Moraine (Cassidy, 1980; Cassidy and Annexstad, 1981; Schutt, 1982; Cassidy *et al.*, 1983; Cassidy and Schutt, 1984).

ANSMET expeditions also have found important concentrations in other regions of Antarctica; the Lewis Cliff-Walcott Neve area of the Beardmore region eventually may rival the Allan Hills icefields in numbers of specimens recovered (Cassidy *et al.*, 1986; Cassidy, 1987) and the Thiel Mountains-Pecora Escarpment region has good potential to produce significant numbers of meteorites (Schutt *et al.*, 1983). Several other less productive areas have been identified as well as a small number of individual meteorite finds (Cassidy, 1977; Cassidy, 1979; Cassidy and Annexstad, 1981; Schutt *et al.*, 1983; Cassidy *et al.*, 1986). Additional meteorite concentration localities undoubtedly will be found in the future. Figure 1 shows the general location of meteorite concentrations and individual finds (modified from Annexstad *et al.*, 1986) in Antarctica. Table 1 is a listing of these areas, the abbreviations used for identifying meteorites found there, and their geographic coordinates. A summary of Antarctic meteorite field work and an overview of recent meteoritic and related glaciological investigations can be found in Bull and Lipschutz (1982) and Annexstad *et al.* (1986).

The mapping of the locations of meteorites found on the antarctic icesheet can play an important role in meteorite and glaciological investigations. Maps are visual aids in pairing studies, especially when fragments of the same fall are found in a given area during different field

seasons. The distribution of meteorites on a given stranding surface may give insights into the concentration mechanism(s) or define areas in which glaciological studies should be concentrated. Thematic maps of meteorite types, masses, terrestrial ages, or combinations of those parameters, will yield additional clues.

Accordingly, we are preparing Antarctic meteorite location maps for the specimens found by the ANSMET project. We have prepared this report to accompany the meteorite location maps that have been completed to date (Schutt *et al.*, 1987a-e). Reduced versions of these maps are shown in the following sections. Meteorite location maps and thematic maps may be ordered from the Lunar and Planetary Institute (LPI). Information for ordering these maps is given in the appendix.

## METEORITE LOCATION MAPS

Yanai (1983, 1984) has published meteorite location maps for the Yamato Mountains and the Allan Hills. The Allan Hills map shows the locations of specimens recovered during the 1976-1977, 1977-1978, and 1978-1979 seasons. The Antarctic Meteorite Location and Mapping Project (AMLAMP) grew out of a need to present the location data that had been acquired in subsequent years by the ANSMET expeditions. Location maps for different regions and meteorite concentration areas are in various stages of development. At this time the Allan Hills-David Glacier Region Map Series is most fully developed.

The first maps of the Allan Hills Main and Near Western Icefields and the Elephant Moraine Icefield were preliminary hand-drawn versions. Subsequently, T. Meunier (U.S. Geological Survey) produced a computer-generated map showing meteorites recovered during the 1982-1983 search of the Far Western Icefield. A copy of the Cartographic Automatic Mapping (CAM) program that was used was acquired from the U.S.G.S. and installed, after modification, into the DEC-VAX computer system at the Lunar and Planetary Institute.

Separate databases have been created for each of the icefields from data contained in the Antarctic Meteorite Newsletter or directly from computer files at the Antarctic Meteorite Laboratory at the Curatorial Facility, Johnson Space Center (JSC) and field and survey data. To date these databases include specimen names, classifications, masses, and location and map data. Terrestrial ages of the

meteorites will be added when a sufficient number have been determined. The databases have been cross-checked for accuracy with the meteorite database computer files at JSC and with the ANSMET database maintained at the University of Pittsburgh. The databases for each of the icefields will eventually be loaded into the System-1032 database environment from which they can be retrieved as a total file or as separate files.

The CAM program is capable of generating maps in many map projections, but by present standards it is a somewhat cumbersome and inelegant program with numerous limitations. Corrections and enhancements have been made to the CAM program, and a utility program was written so that name overprinting is minimized. An interactive editing program is used to finalize name positioning.

Map scales vary as a function of the long dimensions of the icefields, the density of data points that must be presented, and limitations of the CAM program and plotting facilities. Where very high densities of meteorites were found, insets of the area at a larger map scale have been added. Geographic latitude and longitude tick marks are located outside the map borders. North is toward the top of the maps. Geographical features such as bedrock, moraine, and icefield boundaries have been derived from field data and from enlargements of aerial and satellite photographs. These were added by hand to draft versions of the maps, then digitized.

The maps of the Allan Hills-David Glacier Region series are plotted in the Universal Transverse Mercator (UTM) projection. The UTM projection is a conformal, plane rectangular coordinate system. A grid system is placed on the maps as a visual aid in gauging distances and locating specific meteorites. The grid crosses are based on the UTM coordinate system and are at various spacings, depending upon map scale. UTM coordinate values are included on the map for reference. The crosses define grid cells that can be used in locating specific meteorites using an alphanumeric "road map" system. For example, if the location of ALH 84113 is sought, find its grid cell in the listing in the *Near Western Icefield Meteorite Location Map Explanatory Text*. The coordinate pair of the grid cell is F-8. On the map the numbers are found along the north and south margins and the letters along the east and west sides.

## Explanatory Texts

Explanatory texts for the meteorite location maps are found in the following sections. Detailed background, meteorite, and map information specific to each icefield are given. Included are listings of all meteorites recovered from the given icefield, listed by field season, for each of the field seasons during which collections were made (except for the Allan Hills Main Icefield 1976-1977, 1977-1978, and 1978-1979 collections). The meteorite listings contain information current with the date of this publication. Meteorite name, classification, weight, and grid cell coordinates are provided. Also included in the listings is the *Antarctic Meteorite Newsletter* reference [i.e., vol.(no.)] for each meteorite (most recent issue if there are multiple references). Further information on specific meteorites can be obtained from the *Antarctic Meteorites Bibliography Database* maintained on the VAX computer at the LPI as well as the *Antarctic Meteorite Newsletter*.

Icefields with meteorite concentrations are always associated with single or multiple escarpments or step-like topographic features. The upper break in slope generally parallels the long dimension of an icefield and probably strikes perpendicular to the direction of ice sheet flow. Slope profiles are given for each of the mapped icefields in the explanatory texts. These profiles are based on widely spaced survey data and field observations and are therefore only diagrammatic. The profiles were selected in areas where a reasonable amount of survey data was present and they may not be entirely representative of other sections on that particular icefield. The downslope katabatic wind flow, which is responsible for exposing the ice, preventing snow accumulation, contributing to the ablative effects, and the concentration of small meteorite specimens at the downwind ice edge, is generally normal to the escarpments. More complete descriptions of the field settings of meteorite concentrations can be found in Annexstad *et al.* (1986) and Bull and Lipshutz (1982).

## ALLAN HILLS-DAVID GLACIER REGION METEORITE LOCATION MAP SERIES

The Allan Hills-David Glacier region (covered by the U.S.G.S. Antarctica reconnaissance 1:250,000 series Convoy Range and Mt. Joyce maps) of Victoria Land has

been an important source of meteorite specimens since the initial discovery of meteorites at the Allan Hills in the austral summer of 1976–1977. Most of the collection work in the early years of the ANSMET project concentrated on systematic searches of the icefield in the immediate vicinity of the Allan Hills (the Main Icefield), but reconnaissance and subsequent systematic searches of ice patches lying some distance to the west and southwest showed meteorites in significant numbers. These are now called the Allan Hills Near Western Icefield, the Allan Hills Middle Western Icefield, and the Allan Hills Far Western Icefield, because they are geographically distinct from the Main Icefield (Fig. 2). Reconnaissance of the Reckling Moraine Icefield and Elephant Moraine Icefield in 1978–1979 and 1979–1980, respectively, showed that there was good potential for meteorite concentrations at those sites. Subsequent systematic searches there resulted in the recovery of significant numbers of meteorites. There have been single meteorite finds from two locations in the region. One specimen (OTT 80301) was found mixed in with abundant terrestrial material on ice near Outpost Nunatak. Another specimen (ALH 85151) was recovered from a small, isolated icefield 15 km north of the Allan Hills Far Western Icefield (Fig. 2).

Subjective plotting on sketch maps, base maps, and air photos was initially used to document the meteorite locations. In the 1980–1981 season an effort was made to systematically survey the meteorites that were found at the Reckling Moraine Icefield. This surveying has been continued in all subsequent seasons. Crude surveying methods (with an estimated precision of 10 m) were used until late in the 1983–1984 season when a theodolite and electronic distance measuring (EDM) instrument became available. During the 1982–1983 season a satellite surveying instrument was used to make precise position determinations of three base stations at the Allan Hills Far Western Icefield (Cassidy *et al.*, 1983). In the following season, an open survey traverse was made from these points, crossing the Middle Western and Near Western icefields, and ultimately tying into the network established at the Main Icefield by Nishio and Annexstad (1979). Although subject to the accumulation of a large error, this traverse tied the icefields together and provided base stations to which individual meteorite locations could be tied. All survey calculations for the Allan Hills icefields and Elephant

Moraine Icefield involved working in the Universal Transverse Mercator (UTM) coordinate system.

The following maps of the Allan Hills–David Glacier region meteorite location map series have been developed and are currently available: (1) Allan Hills Main Icefield, (2) Allan Hills Near Western Icefield, (3) Allan Hills Middle Western Icefield, (4) Allan Hills Far Western Icefield, and (5) Elephant Moraine Icefield.

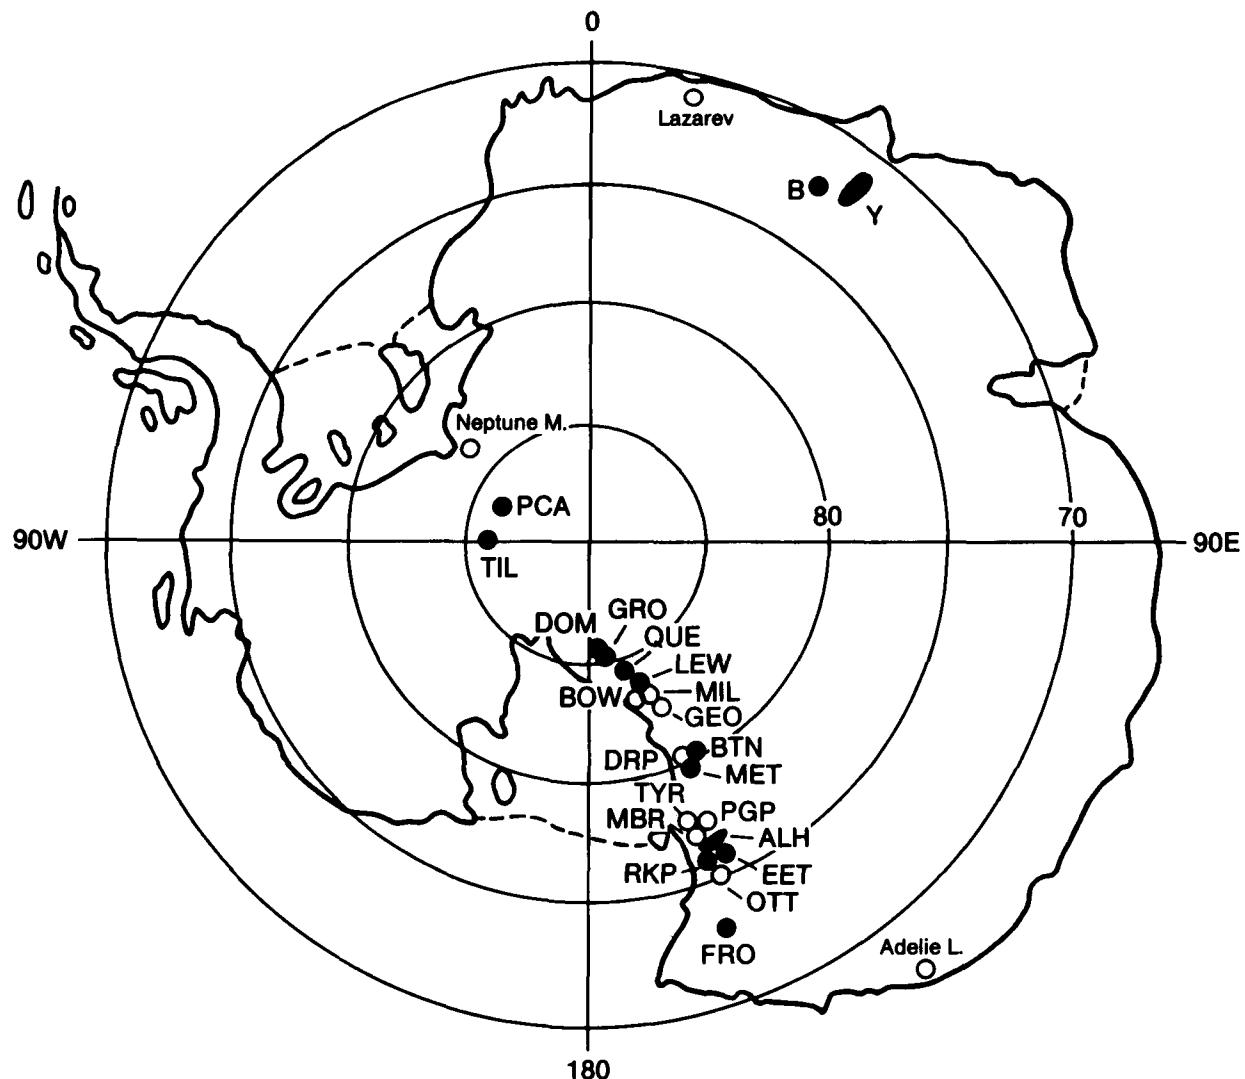

The maps are plotted on 33 in × 44 in (E size) plotting paper. Examples of each of the maps at a reduced scale are included in following explanatory texts. Table 2 is a summary of the numbers of meteorites recovered from each of the mapped icefields from the 1976–1977 through the 1986–1987 seasons.

**Acknowledgments.** The surveying and mapping of the meteorite locations and icefields could not have been accomplished without the assistance and perseverance of ANSMET expedition members during a number of field seasons. Roberta Score provided assistance with the meteorite database. Robert Walker provided the enlargements of the satellite images used in the explanatory texts. Kevin Burke, Kin Leung, and others on the staff of the LPI gave support and advice to the project. The Meteorite Working Group was also forthcoming with encouragement and support. Michael Zolensky offered helpful suggestions and comments. The field work was conducted under National Science Foundation Grants DPP 77-21742, 78-21104, and 83-14496.

## ALLAN HILLS MAIN ICEFIELD METEORITE LOCATION MAP— NORTH AND SOUTH SECTIONS

### 1987 Edition Explanatory Text with Meteorite Listing for the 1979, 1980, 1981, 1983, 1984, 1985, and 1986 Collections

The Allan Hills Main Icefield is located immediately west of the Y-shaped Allan Hills nunatak (Fig. 2). Approximately 75 sq km of ice are exposed on this northward trending icefield. Nearly 22 km long and 7.5 km at the widest point, this icefield has yielded 1005 meteorites. Figure 3 is an enlarged portion of Fig. 2 showing the Main Icefield area and the location of two slope profiles (Fig. 4). Annexstad (1983) and recent studies by Faure and Buchanan (1987) provide detailed descriptions of the Main Icefield area and attempt to explain the meteorite concentration mechanism(s).

The Allan Hills Main Icefield was the first meteorite concentration locality found in the Transantarctic Mountains. At the close of the 1976–1977 field season, a helicopter reconnaissance visit resulted in the recovery of 45 specimens representing 9 individual meteorites. Detailed foot searches in the next two seasons produced 566 specimens. A total of 85 specimens was recovered in random searches during visits to the Main Icefield in the 1979–1980 and 1980–1981 seasons. Systematic searching was continued during the 1981–1982 season when nearly all of the exposed ice area of the Main Icefield was searched in detail or visited on reconnaissance traverses, resulting in 261 specimens recovered. Periodic return visits have resulted in additional finds in the 1983–1984 (28), 1984–1985 (35), 1985–1986 (17), and 1986–1987 (13) seasons.

Yanai's meteorite location map (1984) shows the locations of meteorites recovered during the 1976–1977, 1977–1978, and 1978–1979 seasons. With certain exceptions, detailed in the next paragraphs, the specimens recovered from the Main Icefield in the following seasons for which we have reliable location data are plotted on the *Allan Hills Main Icefield Meteorite Location Map*. In the following listing of meteorites from the Main Icefield table (Table 3) is included showing the types of meteorites recovered and their numbers.

Because of the size of the icefield and the high density of meteorite specimens, two map sections had to be produced. Reduced scale examples of the northern and southern map sections are shown in Figs. 5 and 6. The

areas covered by the northern and southern sections are shown in Fig. 3. There is no overlap between the two map sections.

A small number of meteorites has been found in the vicinity of the Allan Hills or on the Main Icefield areas not covered by the map sections. One specimen (ALH 84243) was found on bedrock in Man Haul Bay, far removed from any ice (Fig. 3). Only one meteorite has been found on the ice in Man Haul Bay (see Yanai, 1984). Seven meteorites (ALHA81037, ALHA81093, ALHA81100, ALH 84056, ALH 84071, ALH 84101, and ALH 85122) have been found on ice during random traverses and searches north of the mapped area besides the meteorite locations on the map by Yanai (1984).

Other meteorites have been found on outcrop, apparently stranded by retreating ice. Three specimens (ALH 85037, ALH 85048, ALH 85123) were found on bedrock 2–4 m above the present ice surface near the southern end of the icefield.

Most of the meteorite locations on the Main Icefield have been referenced to the survey network established by Nishio and Annexstad (1979) or to surveyed geographic features. Field notes and sketch map data were used to document the locations of meteorites found during the 1979–1980 and 1980–1981 seasons. Crude locating or surveying methods (pelorus and snowmobile odometer) were used in the 1981–1982 season. In the 1983–1984 season we began to use a theodolite and EDM to precisely survey meteorite locations. The locations of the 1986–1987 meteorites were obtained from sketch map data provided by G. Faure. All meteorites that were not surveyed with the theodolite/EDM were plotted on a hand-drawn base map. The data points were then digitized along with the geographic features. The map was generated from merged databases of digitized and computed meteorite locations. Therefore, even though most of the meteorite locations not derived from the theodolite/EDM survey are not precisely determined, the locations of those meteorites found within a given season are accurately shown relative to one another. Since there are many precisely determined control stations, the meteorite locations determined by the

different location methods can be constrained so that the map accurately shows the distribution of meteorites on the icefield.

**Acknowledgments.** We thank J. Annexstad, F. Nishio, and L. Ranicelli (1979–1980); J. Annexstad, H. McSween, L. Ranicelli, L. Schultz (1980–1981); G. Crozaz, R. Fudali, and U. Marvin (1981–1982); R. Fudali, A. C. Hitch, K. Nishiizumi, P. Pellis, L. Schultz, and P. Sipiera (1983–1984); C. King-Frazier, S. Sandford, R. Score, R. Walker, and C. Thompson (1984–1985); L. Schultz, E. Zinner, and M. Zolensky (1985–1986) for their contributions to the *Allan Hills Main Icefield Meteorite Location Map*. We also thank D. Buchanan, G. Faure, E. Hagen, and M. Strobel for contributing to the Main Icefield meteorite

collection and mapping project in the 1986–1987 season. Their efforts were supported by NSF Grant DPP 83-14136.

## ALLAN HILLS NEAR WESTERN ICEFIELD METEORITE LOCATION MAP

### 1986 and 1987 Editions Explanatory Text with Meteorite Listing for the 1977, 1981, 1983, and 1984 Collections

The Allan Hills Near Western Icefield ( $76^{\circ}44' S$   $158^{\circ}48'E$ ) lies approximately 12 km west of Main Icefield (Fig. 7). This northwest trending icefield is nearly 14 km long and up to 4 km wide. All areas of exposed ice have been systematically searched and outliers and peripheries visited on a reconnaissance basis. Figure 7 shows the location of two slope profiles diagrammed in Fig. 8.

During the 1977–1978 season, 21 meteorites were recovered from the Near Western Icefield. The location map published by Yanai (1984) gives the names and indicates the locations of these specimens. Since these specimens are not referenced to our survey base station network, they are not included on our map. The positions of the 124 meteorites recovered from the Near Western Icefield during the 1981–1982, 1983–1984, and 1984–1985 seasons are plotted on the Allan Hills Near Western Icefield Meteorite Location Map. A reduced version of the map is given in Fig. 9.

Crude location methods were used during the 1981–1982 season. Most of the specimens found in subsequent seasons were surveyed using the more precise theodolite/EDM system. A preliminary location map was generated using survey data. The data from the 1981–1982 season were then “fitted” to the preliminary map and UTM

coordinates scaled off, entered in the database, and a new location map was generated. Therefore, the map accurately depicts the relative locations of meteorites found in the same season, but somewhat less precisely when locations of specimens from different seasons are compared. The map of the Allan Hills Near Western Icefield is plotted at a scale of 1:12,500. The grid crosses are spaced 1 km apart.

Two editions of the location map have been produced. The most recent version has minor formatting and cosmetic changes and the addition of ALHA81316 to the map and the database.

The listing gives all meteorites recovered from the Allan Hills Near Western Icefield. Following the listing, Table 4 shows the different types of meteorites from the icefield and their numbers.

*Acknowledgments.* We thank G. Crozaz, R. Fudali, and U. Marvin (1981–1982); R. Fudali, A. C. Hitch, K. Nishiizumi, P. Pellas, L. Schultz, and P. Sipiera (1983–1984); C. King-Frazier, S. Sandford, R. Score, C. Thompson, and R. Walker (1984–1985) for their contributions to the Allan Hills Near Western Icefield Meteorite Location Map.

## ALLAN HILLS MIDDLE WESTERN ICEFIELD METEORITE LOCATION MAP

### 1986 and 1987 Editions Explanatory Text with Meteorite Listing for the 1981, 1983, and 1984 Collections

The Allan Hills Middle Western Icefield ( $76^{\circ}50' S$ ,  $158^{\circ}26'E$ ) lies approximately 25 km southwest of the Main Icefield (Fig. 2). This northwest-trending icefield is nearly 20 km long and up to 3.5 km wide. Approximately 30 sq km of ice are exposed. The entire bare ice area has been systematically searched. Figure 10 shows the location of two slope profiles diagrammed in Fig. 11.

Five meteorites were recovered from the Middle Western Icefield on a helicopter reconnaissance search during the 1978–1979 season. No specimen field number or location information was recorded for these. The positions of the 80 meteorites recovered from the Middle Western Icefield during the 1981–1982, 1983–1984, and 1984–1985 seasons are plotted on the Allan Hills Middle Western Icefield Meteorite Location Map. A reduced scale version of the map is given in Fig. 12, and Fig. 10 shows the area covered by the map.

Most of the meteorite locations from the Middle Western Icefield were surveyed using the theodolite/EDM system.

Thus, the relative locations of specimens found and surveyed in different seasons are precisely shown. The map of the Allan Hills Middle Western Icefield is plotted at a scale of 1:25,000. The grid crosses are spaced 2 km apart.

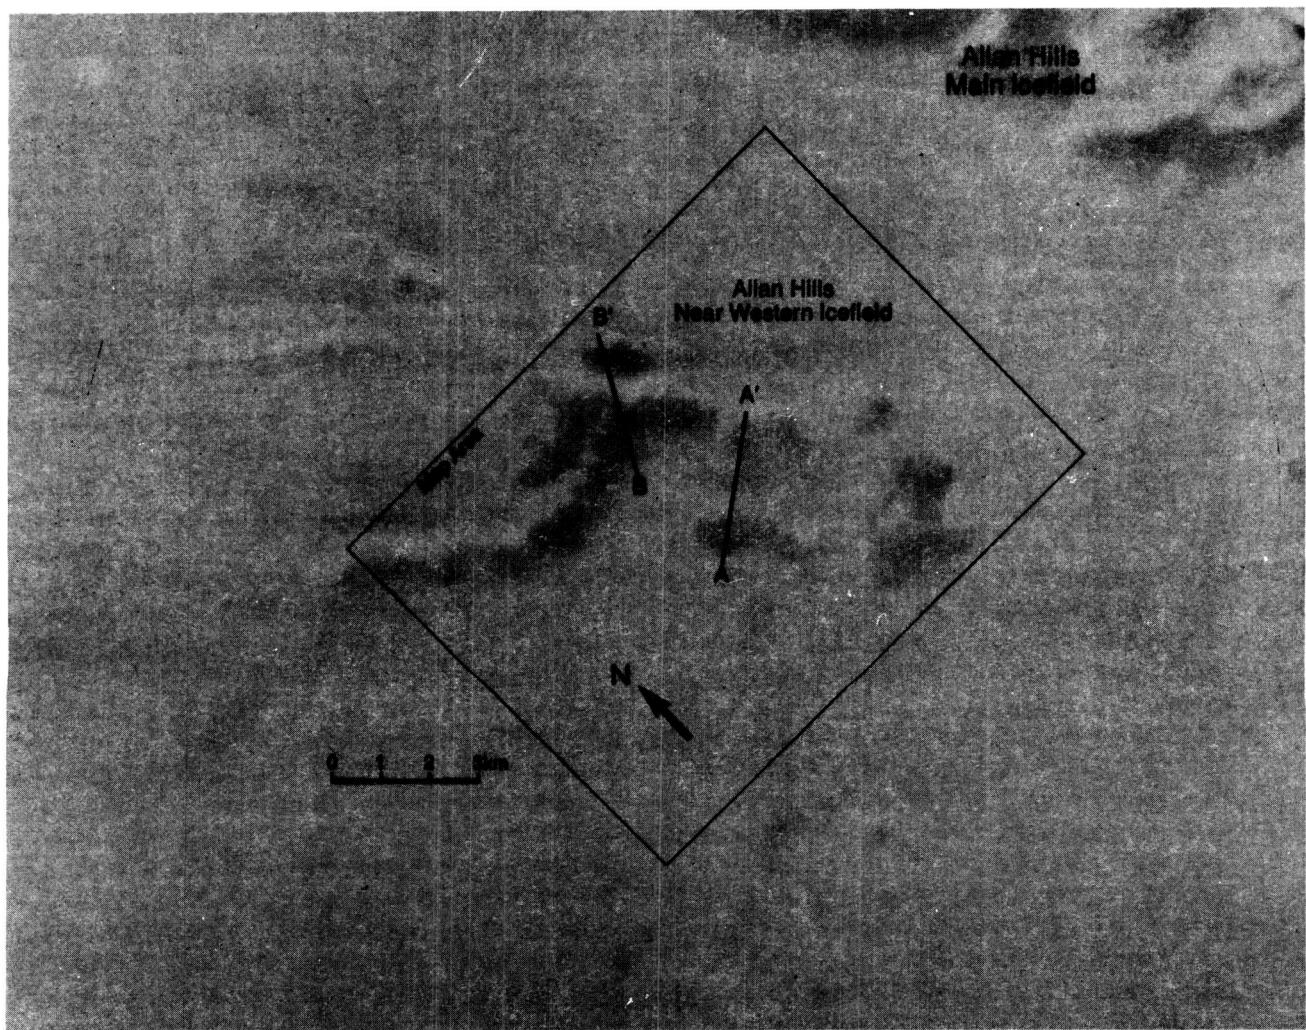

Two editions of the Middle Western Icefield Map have been produced. The second, or 1987, edition has only minor formatting and cosmetic enhancements and no additions or deletions of meteorite locations. A listing of all specimens found on the Middle Western Icefield, with the exception of the 1978–1979 specimens, follows. The types of meteorites and their numbers are given in Table 5.

**Acknowledgments.** We thank I. Whillans (1981–1982); R. Fudali, A. C. Hitch, K. Nishiizumi, P. Pellas, L. Schultz, and P. Sipiera (1983–1984); C. King-Frazier, S. Sandford, R. Score, C. Thompson, and R. Walker (1984–1985) for their contributions to the Allan Hills Middle Western Icefield Meteorite Location Map.

## ALLAN HILLS FAR WESTERN ICEFIELD METEORITE LOCATION MAP—EAST AND WEST SECTIONS

### 1986 and 1987 Editions Explanatory Text with Meteorite Listing for the 1982, 1983, 1984, and 1985 Collections

The Allan Hills Far Western Icefield ( $76^{\circ}54'S$   $157^{\circ}01'E$ ) is a large bare ice area lying approximately 70 km southwest of the Allan Hills (Fig. 2). This sinuous appearing icefield, trending northwest, is nearly 45 km long and up to 8 km across at its widest point. Approximately 100 sq km of ice are exposed. Slope profiles (Fig. 13) are given for three locations (Fig. 14).

The Far Western Icefield was first visited during the 1982–1983 season and systematic searches were made in selected areas with 45 meteorites recovered. One meteorite (ALH 82102) was discovered in the process of emerging from the ice. A satellite surveying instrument was employed during this season to determine base station locations used in the meteorite location surveys. These points potentially can be used in the study of ice movement rates. A brief visit was made during the 1983–1984 season mainly to collect ice samples and begin the survey traverse that connected all the Allan Hills icefields. Systematic searches of virtually the entire blue ice area were made in the following two field seasons.

The positions of the 317 named meteorites collected from the Far Western Icefield are plotted on the *Allan Hills Far Western Icefield Meteorite Location Map*. Because of the map scale that was desired and the size and orientation of the icefield, two map sections had to be generated. These are designated the West and East sections. Figures 15 and 16 are reduced scale versions of the two sections. Figure 9 shows the areas covered by the map sections. The map scale is 1:25,000 and the UTM grid cell crosses are spaced 2 km apart.

Crude surveying methods were used to determine meteorite positions during the 1982–1983 season. In subsequent seasons most of the meteorite locations and the 1982–1983 base stations were surveyed with the theodolite and EDM. Thus, the relative locations between the 1982–

1983 specimens and all the others are not precise. The locations of several meteorites (ALH 82109, ALH 82116, ALH 82137, ALH 83105, ALH 83108, ALH 84221, ALH 85004, and ALH 85012) were determined only very generally, and placements on the map are therefore approximate. In the 1983–1984 season two carbonaceous chondrite strewn fields were found near the southern end of the icefield. In the larger of the two, 56 fragments were recovered. These have been paired and are named ALH 83100. The general outline of this strewn field is shown on the map. The location of ALH 83102 was the site of a smaller strewn field consisting of 21 paired fragments. A listing of the Far Western Icefield meteorites is given in the following section including a table (Table 6) giving the types of meteorites found there and their numbers.

Two editions of the *Allan Hills Far Western Icefield Meteorite Location Map* have been generated. The 1986 edition of the maps overlaps 7.5 cm where the two sections adjoin. This was eliminated from the 1987 edition. Other changes have also been made on the 1987 edition: (1) minor format and cosmetic changes; (2) deletion of the ALH 85116 specimen location, which turned out to be a terrestrial rock; (3) correction of the ALH 83100 strewn field designation in the legend and addition of ALH 83100 to the map; and (4) elimination of the 7.5 cm overlap between the east and west sections.

**Acknowledgments.** We thank T. Meunier and C. Thompson (1982–1983); R. Fudali, A. C. Hitch, K. Nishiizumi, P. Pellas, L. Schultz, and P. Sipiera (1983–1984); C. King-Frazier, S. Sandford, R. Score, C. Thompson, and R. Walker (1984–1985); L. Schultz, E. Zinner, and M. Zolensky (1985–1986) for their contributions to the *Allan Hills Far Western Icefield Meteorite Location Map*. Tony Meunier provided location data for the 1982–1983 meteorites and satellite positioning derived base station coordinates.

## ELEPHANT MORaine ICEFIELD METEORITE LOCATION MAP

### 1986 and 1987 Editions Explanatory Text with Meteorite Listing for the 1979, 1982, 1983, 1984, and 1986 Collections

Elephant Moraine is an unusual, isolated surficial moraine not associated with exposed bedrock and lying along an escarpment running westward from Reckling Peak (Fig. 2). Bare ice areas surround the moraine. In the vicinity of the moraine, upward of 50 sq km of ice are exposed. Elephant Moraine consists of a thin veneer of rocks lying on ice. The moraine has a general northward trend, normal to the escarpment and is streaming to the north with the ice flow toward the David Glacier (Figs. 17 and 18). Elephant Moraine and the similar Reckling Moraine have been the focus of studies by Gunter Faure and coworkers (*Faure and Taylor, 1985; Faure et al., 1987*).

Ten meteorites were collected on a reconnaissance visit in the 1979–1980 field season. A brief period during the 1982–1983 season was spent in systematic searching. Virtually the entire bare ice area covered by the location map was systematically searched or visited on a reconnaissance basis during the 1983–1984 season. Small collections were made in the 1984–1985 and 1986–1987 seasons by the parties studying the moraine.

During the 1982–1983 season a reconnaissance trip was made to the icefields west and northwest of Elephant Moraine. The icefields 20–35 km west of Elephant Moraine (Fig. 2) appear to be associated with a continuation of the Reckling Moraine-Elephant Moraine escarpment. From this area six meteorites (EET 82604, EET 82609, EET 82610, EET 82614, EET 82615, and EET 82616) were recovered. The icefield 35–60 km northwest of Elephant Moraine (not shown on Fig. 2) was visited briefly and two meteorites (EET 82608 and EET 82612) were collected.

The locations of 234 of the 236 meteorites collected from the vicinity of Elephant Moraine in the 1979–1980, 1982–1983, 1983–1984, and 1984–1985 and 1986–1987 seasons are plotted on the Elephant Moraine Icefield Meteorite Location Map. A reduced scale example of the map is shown in Fig. 19. Map scale is 1:12,500 and grid crosses are on 1 km spacings. Two editions of the map have been produced. The following changes have been made

in the 1987 edition: (1) addition of the three 1986 specimens; (2) deletion of terrestrial samples EET 83313, EET 83327, EET 83332, and EET 83381 from the map and meteorite databases; (3) addition of EET 83403 to the map and meteorite databases; (4) combined location of two mapped fragments of EETA79007 to one representative location; and (5) minor format and cosmetic enhancements.

The locations of meteorites found on the 1979–1980 reconnaissance trip were approximately plotted on aerial photographs. The locations of meteorites found in succeeding seasons were determined by crude surveying methods. Thus, only the relative positions of meteorites found within a given season are shown accurately. A theodolite and EDM were used to establish precise control positions of the 110, 115, and Elephant stations relative to the satellite-surveyed Dr. Seuss base station. The meteorite locations, the moraine edges, and ice/firn boundaries were plotted by hand on a base map and then digitized. A listing of the meteorites recovered from the Elephant Moraine Icefield follows and includes a table (Table 7) of the types of meteorites recovered and their numbers.

**Acknowledgments.** We thank J. Annexstad, L. Benda, and L. Rancitelli (1979–1980); V. Buchwald, T. Meunier, and C. Thompson (1982–1983); R. Fudali, A. C. Hitch, K. Nishiizumi, P. Pellas, L. Schultz, and P. Sipiera (1983–1984); and S. Sandford (1984–1985). Thanks also to G. Faure and K. Taylor for their assistance in 1984–1985 and D. Buchanan, G. Faure, E. Hagen, and M. Strobel for their contribution to the Elephant Moraine meteorite collection and map in the 1986–1987 season. Tony Meunier provided the satellite positioning data.

## APPENDIX. METEORITE LOCATION MAP AND THEMATIC MAP ORDERING INFORMATION

The icefield maps currently included in the Antarctic Meteorite Location Map Series, their scales, and number of sheets per icefield are shown below.

**TABLE A1. Icefield maps currently included in the AMLAMP series.**

Icefield	Scale	Sheets
Allan Hills Main	1:10,000	2
Allan Hills Near Western	1:12,500	1
Allan Hills Middle Western	1:25,000	1
Allan Hills Far Western	1:25,000	2
Elephant Moraine	1:12,500	1

Thematic maps are produced according to a requestor's design specifications as described in a thematic map design form. To design a thematic map, the requestor is first asked to specify the icefields to which the design is to be applied by marking the appropriate field. Next, a map title may be supplied that will be included in the legend box of the

specified maps. A requestor is allowed to select up to six thematic definitions and to associate a unique colored symbol with each theme. These symbols will be placed on the specified icefield maps to designate the meteorites that represent each of the selected themes. At present, thematic map parameters are limited to meteorite classifications and meteorite specimen weights, but as information is acquired, terrestrial age options will be made available for map design. Classification theme definitions may be specified explicitly (i.e., "H-5 CHONDRITE") for a narrow scope or by using the wildcard specifier (i.e., "\* CHONDRITE") for a broader scope. The wildcard specifier, "\*", may appear anywhere and any number of times in a thematic definition. The form and terminology of the Antarctic Meteorite Newsletter should be observed when specifying classification theme definitions. Symbol color and type are specified by selecting the desired number from the available colors and types listed at the bottom of the form.

If you would like to order the meteorite location map set or request thematic maps, please complete the Thematic Map Design and/or the AMLAMP Map Request Forms. All maps will be sent rolled in mailing tubes.
